CONTENTS

ACKNOWLEDGMENTS

The research described in this report resulted from a project funded by the Water Research Commission and the University of the Orange Free State, entitled:

"Enhancement of the National Ground-water Data Base Facilities".

The Steering Committee responsible for this project, consisted of the following persons:

Mr. A.G. Reynders	Water Research Commission (Chairman)
Mr. P.W. Weideman	Water Research Commission (Secretary)
Mr. H.M. du Plessis	Water Research Commission
Prof. H.J. Potgieter	University of the Orange Free State
Dr. D.B. Bredenkamp	Department of Water Affairs and Forestry
Mr. J.D. du Toit	Department of Water Affairs and Forestry
Dr. M.C. Dent	Computing Centre for Water Research (CCWR)
Mr. J. Easton	Chamber of Mines of South Africa
Mr. M.D. Piche	Borehole Water Association

The financing of the project by the Water Research Commission and the University of the Orange Free State, and the contributions of the members of the Steering Committee are gratefully acknowledged.

Many individuals, organizations and companies have contributed to the success of this project by suggestions for enhancement of the software and other constructive criticism. Without them, the value of the final product would have been reduced significantly. The Department of Water Affairs and Forestry has to be mentioned specifically for their assistance during this project.

Personnel of the Institute for Ground-water Studies are thanked for assistance and making programmes available for this project.

1 INTRODUCTION

In 1987, the Institute for Ground-water Studies (IGS) at the University of the Orange Free State completed the development of a National Ground-water Data Base (NGDB) facility on the mainframe computer of the Department of Agriculture in Pretoria. This was a three-year research contract between the Institute for Ground-water Studies, the Department of Water Affairs and Forestry (DWAF) and the Water Research Commission (WRC). Upon completion of this contract, it was felt that additional software would be required to enable the geohydrologist to enter and process the data within the data base and display this information in the form of graphs and tables. In this respect, it was felt that the existing G-Base software, which has been developed in-house at the IGS, could serve as a basis for enhancing the NGDB. Subsequently, a follow-up research programme was motivated by the Institute for Ground-water Studies. The aims of this study were:

- Determine requirements of users for the immediate future.
- Update of software written for the previous project, according to requirements of users.
- Adapt software to match hardware requirements.
- Train people concerned with ground water to generate information for input into the data base.
- Actively promote the use of the data base facilities by giving demonstrations, distributing brochures and presenting papers.
- Train personnel in the DWAF, so that they would continue with geohydrological data base programming and data input after this project ceased.
- During this time, the DWAF would continue to do data base programming for the existing ground-water data base (NGDB).

These aims can conveniently be combined into the following main points:

- The *enhancement* of the National Ground-water Data Base (NGDB) facilities by providing suitable software for the interpretation of data in the data base.

- The identification of *needs* amongst data base users and accommodating these needs within the present research project.

- Active *promotion* of the use of the NGDB facilities amongst geohydrologists and others interested in ground water and related data.

Details on work completed during this exercise are available in two volumes, namely:

Volume 1 : User's Manual for the NGDB.
Volume 2 : HydroCom Manual.

Both these volumes are technical manuals, and are intended for use only by those working with either of the two data bases. Further details on these can be obtained from the IGS.

This executive summary is accompanied by a demonstration diskette, which should, together with the summary, provide sufficient information for the non-data base user.

2 STRUCTURE OF THE NGDB AND HYDROCOM

2.1 The NGDB

The NGDB on the mainframe computer in Pretoria has not been altered in any significant way from that which was developed by Cogho *et al.* (1989). The structure of the NGDB is illustrated in Figure 1.

Since the completion of their research, the numbers of sites in this data base have increased from approximately 35 000 to more than 100 000. The Department of Water Affairs and Forestry, in particular, has been entering vast amounts of data into the data base. Water levels as digitized monthly from continuous strip chart recorders, comprise a large portion of the data presently within the data base.

Presently, only the Department of Water Affairs and Forestry has direct access to the data base. Others may request information on diskette. It is envisaged that this situation will continue to exist, because:

- very few organizations, institutions or individuals are linked to the mainframe,

- ground water is regarded as private water under present South African legislation and not everybody may have direct access to the data base facility,

- the system whereby data are requested through the Director, Directorate of Geohydrology, Department of Water Affairs and Forestry, is presently functioning satisfactorily, and

- not everybody has the technical expertise to interact with the data base via a terminal.

The NGDB, in its present form, is primarily intended to store data into an organized structure, from where this data can be accessed and withdrawn with the provision of certain variable specifications. A large range of specifications is possible, of which the most important are:

- Extraction of data by area
- Extraction of data by date
- Extraction of data by site numbers.

The NGDB does not allow processing of this data in any way. It merely writes data, which fall within the specified range, to a file that can later be accessed for visual inspection, or which can be processed by the HydroCom package.

2.2 HydroCom

HydroCom is the name for an ensemble of programs that has been written during the course of the present research contract. In total, it comprises more than 300 different programs, all linked together, so that passing from one programme to the other becomes transparent to the user. In size, these programmes constitute about 4 Mbyte. This software is presently available on 4 high-density diskettes and can only be run after installation of the software onto a hard disk in an IBM compatible computer.

The HydroCom software consists of two basic units, namely HydroBase and HydroCad. HydroBase is the equivalent of the NGDB on the mainframe in Pretoria. All the variables that may presently be entered into the NGDB may also be entered into the HydroBase module. The HydroCad portion is used to display the data as various graphs and maps. Examples of output from HydroCom are included in Appendix A.

2.2.1 HydroBase

The HydroBase data base has been written in Clipper and all data base files are therefore dBase III compatible. As far as possible, the same data base structures, as in the case of the NGDB, have been provided for within HydroBase. The screen layouts are different though, because of better screen handling facilities that are available on IBM compatible computers.

A major difference between HydroBase and the NGDB is that HydroBase allows entry of many additional variables, such as surface hydrology, full weather station information and data, water quality data and user selectable variables.

The addition of these data bases to the HydroBase data base is the result of requests received from the geohydrological community for these variables to be added to the data base. It was felt that ground water could not be studied in isolation from surface water, meteorological data and water quality. The present HydroBase structure is illustrated in Figure 2.

In view of the comprehensive list of hydrological variables that may be entered into HydroBase, this data base, in its present structure, provides the geohydrologist, as well as the surface hydrologist, hydrochemist, water resources developer and geologist with the means to cross-correlate between these different disciplines. On mainframe computers in Pretoria, the information relating the different disciplines is presently stored in separate data bases. There are for instance:

- the National Ground-water Data Base
- the HIS Data Base for Surface Water
- the Water Quality Data Base
- the Pollution Monitoring Data Base
- the Meteorological Data Base by the Weather Bureau, and
- the Geological Data Base by the Geological Survey.

These data bases are presently not interlinked and it is therefore impossible for the researcher to combine and process data from these data bases simultaneously.

In HydroBase, however, once the data have been incorporated within the data base, several means of simultaneous processing of interrelated data become available. Because of this facility which HydroBase provides, it is envisaged that compatibility between

HydroBase and some of the above-mentioned data bases will, in future, be established. Presently, HydroBase is fully compatible with the NGDB and about 60 per cent compatible with the National Water Quality Data Base.

2.2.2 HydroCad

Graphic displays of data, the drafting of maps and depicting data within the data base on these maps, have always been considered a high priority of the present research project. Several graphics drivers were available at the outset of this project. After inspection of the facilities and opportunities presented by each of these packages, it was decided to standardize on a CAD driver that, at that stage, held several advantages above other existing packages. Some of these are:

- The CAD drivers have been developed locally and the development of additional drivers, should this become necessary for the present investigation, would be possible.

- Permission was granted by suppliers of the CAD software that it may be incorporated into the HydroCom module, with the proviso that royalties will be paid on each package provided to an end-user.

- Editing tools to display graphs and edit them afterwards, are available through the CAD system.

The present structure of the graphics programmes, developed during this contract and how they interrelate with the total software package, is depicted in Figure 3. The programmes to draw and analyse data from the data base are interlinked and switching from one programme to the other is transparent to the user.

2.2.3 HydroCom usage

HydroCom, apart from being the package to process NGDB data, can operate as a data base on its own. The format of the data within HydroCom is compatible with that of the NGDB and any data presently entered into the HydroCom System, can be transferred to the NGDB. HydroCom can therefore be regarded as the intermediate data base solution to those individuals and companies who do not have direct access to the NGDB facilities or who wish to keep their data separate from that on the NGDB.

To date, more than 60 HydroCom packages have been implemented on IBM compatible computers throughout Southern Africa.

An interesting pattern has developed amongst the users of these data base facilities. A large percentage is individuals or organizations outside the field of geohydrology. This creates an additional awareness of the importance of water conservation.

3 DATA CAPTURING PROCEDURES

The Department of Water Affairs and Forestry and the Institute for Ground-water Studies have routinely entered data into the NGDB since 1987. Since 1989, the Institute for Ground-water Studies has not been contributing data to the NGDB, but has been entering new data into the HydroCom System, as part of the present system.

Water levels from continuous strip chart recorders, as well as levels measured by hand, have contributed to by far the largest portion of the data presently available on the NGDB. The strip charts are digitized at the Department of Water Affairs and Forestry and after verification of the data, it is added routinely to the NGDB.

Data capturing within HydroCom is accomplished by making a series of selections from menus on the computer screen. Data are usually entered into various subdirectories in which data for specific clients, aquifers or drainage basins will be kept separately. It is the responsibility of the individual, working with the data base, to ensure that his or her data are of high quality as very few checks have been built into the HydroCom System. Certain information, such as the site type and the co-ordinates of a site, must be provided before subsequent information may be entered. Once the essential information for a specific site has been entered, practically unlimited amounts of information relating to the site may be entered. The only limitation in this respect is the capacity of the hard disk in the personal computer. Data are automatically sorted and indexed.

4 DATA REQUEST FROM THE NGDB

A request for data contained within the NGDB may presently be made to:

The Director
Directorate of Geohydrology
Department of Water Affairs and Forestry
Private Bag X313
PRETORIA 0001

Details on data conversion from the NGDB format to the HydroCom format are provided in a README.DOC file which comes with the data conversion programme.

More details on the information required by the Directorate of Geohydrology during a request for data are provided in Chapter 6.

5 DATA SUBMISSION TO THE NGDB

Presently, all data submission to the Department of Water Affairs and Forestry is on a voluntary basis. Those individuals and institutions that are not using the HydroCom software, are free to submit information in any form available, such as geohydrological reports, for instance. The Department of Water Affairs and Forestry has forms available for those who would like to submit information in an acceptable form directly into the NGDB.

Those who have data within a subdirectory of HydroCom and who wish to submit this data for incorporation into the NGDB, will obtain more information on data submission procedures in the README.DOC file on the data conversion diskette.

6 MANAGEMENT OF THE NGDB

6.1 Introduction

A data base manager has been appointed by the DWAF. This is an important link in the future successful administration of the NGDB. Apart from this manager, support staff to provide in the back-up facilities for data entry and verification of data are also available within the DWAF.

6.2 Tasks of the Data Base Manager

6.2.1 Data input co-ordination

The quality of the data within the NGDB has to be of a high standard at all times. All data therefore have to be scrutinized, before they are finally incorporated in the NGDB.

One of the main functions of the data base manager and his team is therefore the verification of especially data that are to be transferred from HydroCom. During uploading of HydroCom data, the following actions are required:

- Verification of the HydroCom data
- Query and rectify HydroCom data which cannot be verified
- Check for duplicates of HydroCom and NGDB data
- Import of HydroCom data into the NGDB.

6.2.2 Requests for data

Requests for data by organizations or individuals outside the Department of Water Affairs and Forestry should be addressed to the Director of the Directorate of Geohydrology, for attention of the data base manager.

The following information must be provided within such a request:

- The name of the institution requesting the information
- The purpose for which this information will be used
- The area for which information is requested
- A variable list
- Starting date and end date of data sequence
- An indication of whether or not this data will be processed by means of the HydroCom software package

- If processed by means of the HydroCom package, whether or not the eventual data base will again be made available for use by the Department of Water Affairs and Forestry

- Whether or not reports relating to the data provided will be made available to the Department of Water Affairs and Forestry.

After consideration of a request for data from the NGDB, the Director of the Directorate of Geohydrology will have the authority to make available, or refuse the data. Should the data be made available, this will be dispatched in the form of a computer diskette, in an ASCII file, which may be transferred to the HydroCom package.

A charge may be made for services rendered by the Directorate of Geohydrology and for computer time.

6.2.3 Overviews

An important facet of any data base is the production of information circulars, specifying what data are available and what the end-user can expect and gain by making use of this information. The data base manager should issue annual reports specifying progress with data entry, providing statistics on interesting aspects regarding data capturing and also a discussion of scientific achievements during the year by people using the NGDB facilities.

The data base manager should actively promote the use of the NGDB and encourage users to submit data to the NGDB.

6.2.4 Assistance and training

Many people may presently not be using the NGDB facilities, because of a feeling of uncertainty with regard to what the data base can do for them. The data base manager should be in a position to provide assistance and training to individuals requiring such services. Regular workshops should be organized during which hands-on training in the use of the NGDB and the HydroCom software will be provided.

7 RECOMMENDATIONS

Development and quality control relating to data base management will continue for as long as the data base exists. The following recommendations are made with this view in mind:

- A technical committee, constituting geohydrological experts in various fields, under chairmanship of the Director of Geohydrology, should be established. Their main task should be extension and enhancement of the existing data base facilities, as the need arises.

- The tasks of the data base manager, as described above, should be revised annually by the technical committee with the aim to encourage usage of the data base facilities.

- The use of either the NGDB or HydroCom should be made a condition of all ground-water projects within the DWAF and the Water Research Commission.

8 SUMMARY AND CONCLUSIONS

The study spanned three years of research and development and the main benefits deriving from this work, can be summarized as follows:

- The NGDB facilities on the mainframe computer have been supplemented by the creation of an equivalent data base system which runs on IBM compatible personal computers.

- A link has been provided between the NGDB and HydroCom, so that data may be extracted from the NGDB and used within HydroCom.

- Data may also be entered directly into HydroCom, and later be uploaded to the NGDB, under supervision of the NGDB manager.

- All data processing and creation of displays, such as graphs and maps, are performed within the HydroCom package and not within the NGDB. The latter is merely a data storage facility.

- Apart from ground-water data, HydroCom also allows entry and processing of hydrological, meteorological and hydrochemical data.

- Many individuals within the private and public sectors, have contributed ideas for the enhancement of the data base during the past three years. These suggestions have all been incorporated within the HydroCom package.

- Active promotion of the use of the HydroCom package, in conjunction with the NGDB, has been an ongoing feature of this project. Brochures have been printed and distributed, demonstrations given at conferences and private tuition given in the use of the software.

- The HydroCom package is presently being used in more than 80 ground-water projects throughout South Africa, by the Directorate of Geohydrology, mining companies, other industries and ground-water consultants.

- Information regarding the NGDB may be obtained from: The Director, Directorate of Geohydrology, Department of Water Affairs and Forestry, Private Bag X313, Pretoria 0001. Information on HydroCom may be obtained from: The Director, Institute for Ground-water Studies, University of the Orange Free State, P.O. Box 339, Bloemfontein 9300, South Africa.

O Owner's record
R Report or file
P Pump operator's record
No information

Method of Development

A Pumped with air lift (no inductor)
B Bailed
C Compressed air
I Air lifted with inductor
J Jetted or washed
N None
P Pumped
S Surged
No information

Type of Finish

B Brickwork
C Porous concrete
F Filter (gravel pack with perforations)
G Gravel pack with screen
H Horizontal gallery
O Open bottom (partially cased)
P Perforated or slotted
S Screen
W Well point
X Open hole
Z Other
No information

Special Development Treatment

B Brushing
C Chemical (acid, etc.)
D Dry ice
E Explosives
H Hydrofracturing
Z Other
No information

Hole Casing and Piezometer

Material

B Brass
C Concrete
D Copper
P PVC
O Plastic
S Steel
X Stainless steel
Z Other material
No information

Type of Openings

F Perforated or slotted with fibre mesh
M Mesh screen
P Perforated or slotted
S Screen
W Well point
X Open hole
Z Other
No information

Method Openings Made

A Sawn
D Drilled
E Electric cut
G Gas cut
M Machine cut
P Punched
S Screen
W Well point
X Wire wound
Z Other
No information

Fill Material

Type of fill

B Bentonite or clay
C Cement
G Gravel (> 2mm)
S Sand (≤ 2mm)
X Bottom closed
No information

Equipment

Type of Installation

A Airlift
C Centrifugal pump
G Gravity suction
H Hand pump
J Jet
M Mono-type pump
N No equipment
O Observation tube
P Piston pump
Q Powerhead
R Recorder
S Submersible pump
T Turbine
W Windpump
X Windpump with powerhead
Z Other
No information

Type of Power

D Diesel engine
E Electric motor
H Hand
W Windpump
Z Other
No information

Monitoring Facility

A Airline
I Piezometer inside casing
O Piezometer outside casing
T Pressure Transducer
No information

Information Source

See Basic Information

Reservoir Type

C Cement dam
E Earth dam
P Pond
T Tank
Z Zink dam
No information

Discharge Rates

Type of discharge

F Flow
P Pump
No information

Method Discharge Measured

C Current meter
E Estimated
F Flume
M Totalling meter
N Notch (V- or U-notch)
S Submerged orifice
V Volumetric measurement (container + stop-watch method)
U Venturi meter
W Weir
Z Other
No information

Information Source
See Construction

Water Levels

Method Measured

A Airline
E Electrical contact meter
P Pressure gauge measurement
R Recorder
S Steel tape
U Reported, unknown
X Estimate
No information

Water-level Status

A Water level affected by near-by pumped hole or drilling
D Dry
F Flowing
O Obstruction, no water level measured
P Pump water level
R Recovering water level
S Static water level
No information

Pumping Tests

Method Tested

A Air test
B Bailer test
F Free flow test
O Owner test
P Controlled pumping test (step or main)
R Pumping test with recovery
S Slug test
No information

Borehole Geophysics

Information Source

F Field checked
G Geophysicist
M Memory
O Owner's record
R Report or file
No information

Instrumentation

Type of installation

C Conductivity probe
G Gas sampler
H pH probe
L Water-level recorder
M Measuring weir
P Pump
R Rain gauge
S Water sampler
T Temperature probe
W Weather station
Z Other
No information

Information Source

C Construction data
F Field checked
G Geologist, technician
H Hydrologist
M Memory
O Owner's record
R Report or file
P Pump operator's record
No information
